**Abstract**— In this paper, a lumped parameter model applied to simulate charge–discharge cycle of the hydrogen storage device filled with  $MmNi_{4.6}Al_{0.4}$  using MATLAB. In this study, a simplified lumped model employs general mass and energy balance equations is developed and validated by comparing the simulations to the experimental data available in the literature. The numerical results show that the predicted hydrogen storage for several parameters such as pressure and temperature is in a good agreement with the experimental data.

**Keywords**— Hydrogen storage, Metal hydride, Heat and mass transfer.

## I. INTRODUCTION

Hydrogen is the most common element in the universe and is an ideal candidate as fuel source (its molecule has the highest energy content per unit weight of any known fuel). Hydrogen can be stored as (i) compressed gas, (ii) cryogenic liquid, (iii) solid fuel as chemical or physical combination with materials, such as metal hydrides, complex hydrides and carbon materials.

Metal hydride based hydrogen storage systems offer higher volumetric density and better safety compared to conventional methods such as compression or liquefaction of hydrogen. Metal hydride is used to supply hydrogen to the fuel cell in many applications. However, on-board hydrogen storage is one of the major issues that need to be resolved. Experimental investigation to determine the reaction kinetics, equilibrium pressure, and thermal conductivity of hydride bed during both absorption and desorption processes have been performed [1]. The basic phenomena which underlie hydrogen absorption and desorption in metal hydrides have long been studied [2], with special focus on their kinetic characteristics, which have been thoroughly analyzed by means of experimental investigations and numerical models. Hydrogen storage has been the subject of intensive research for many years, according to the previous studies. [4-11] developed a 2D and 3D mathematical model for heat and mass transfer in compact cylindrical reactors.

Complicated reactor geometries have been considered, such as an annular metal hydride bed surrounded on both sides by cooling fluid [12], or two concentric annular beds both surrounded by cooling fluid [13], or multiple heat transfer tubes and filters embedded in the metal hydride bed in a cylindrical container [14], in order to provide more insight into absorption kinetics by approaching the working conditions of a real metal hydride storage system.

In a classical lumped model equations describing mass and heat transfer are ordinary differential equations (ODEs) rather than partial differential equations (PDEs). The dependent variables, such as mass absorbed and temperature, are function of time alone and independent of the position (x,y,z) in the reactor.

Therefore, in this study, a lumped model is applied to investigate the effects of various parameters on the hydrogen absorption of alloy fills the space between the filter (inner wall of hydride bed) and the inner concentric tube of the reactor. Hydrogen is supplied into the bed radially through a porous filter, as shown in figure 1.

Fig. 1. Original scheme of the storage system, taken from [1].

### Nomenclature

$A$	cell geometric area, m <sup>2</sup>
$C_a$	constant rate for LaNi <sub>5</sub> , 1/s
$C_p$	specific heat, J/kg K
$D_p$	metal hydride particle diameter, m
$E_a$	activation energy, J/mol H <sub>2</sub>
$R$	universal gas constant, J/mol K
$h$	heat transfer coefficient, W/m <sup>2</sup> K
$k$	thermal conductivity, W/m K
$K$	permeability (m <sup>2</sup> )
$M$	metal hydride
$P$	gas pressure, bar
$P_{eq}$	equilibrium pressure, bar
$t$	time, s
$T$	temperature, K

### Greek letters

$\Delta H^{\circ}$	reaction heat of formation, J/kg
$\varepsilon$	porosity
$\mu$	dynamic viscosity, kg/m s
$\rho$	metal or gas density, kg/m <sup>3</sup>
$\varphi$	heat transfer rate, W/m <sup>2</sup>
$\rho$	

### Subscripts

$eff$	effective
$eq$	equilibrium
$g$	gas phase (hydrogen)
$S_s$	saturation
$S$	solide
$f$	fluide cooling

## II. MATHEMATICAL MODELLING

The system is consisted of a cylindrical tank filled with porous MmNi<sub>4.6</sub>Al<sub>0.4</sub> and with a cooling (heating) system during absorption (desorption), water was chosen as the heat transfer fluid. A mathematical model was developed to evaluate the transient heat and mass transfer in a cylindrical metal hydride tank and predict the time-varying temperature field and mass of hydrogen stored, as a function of the thermal conductivity of the enhanced hydride material, and thermal boundary conditions. In order to simplify the model, some assumptions have been made. The assumptions made in the present model are as follows: (1) temperature is uniform in the tank; (2) hydrogen is regarded as an ideal gas; (3) local thermal equilibrium is assumed between the solid metal and hydrogen gas; (4) the effect of pressure variation in the tank is negligible; and (5) thermal and physical properties are considered independent of bed temperature and concentration.

### II.1. Mass balance for hydrogen

The balance of mass equation for hydrogen may be written as follow:

For absorption:

$$\frac{dm_{H_2}}{dt} = -SC \cdot m_{MH} \cdot \frac{MW_{H_2}}{MW_{MH}} \frac{dx}{dt} + \dot{m}_{in} \quad (1)$$

For desorption:

$$\frac{dm_{H_2}}{dt} = -SC \cdot m_{MH} \cdot \frac{MW_{H_2}}{MW_{MH}} \frac{dx}{dt} - \dot{m}_{out} \quad (2)$$

### II.2. Mass balance for metal hydride

The balance of mass equation for metal hydride for absorption or desorption may be written as follow:

$$\frac{dm_{MH}}{dt} = m_{MH} \frac{dx}{dt} \quad (3)$$

### II.3. Kinetic reaction

The amount of hydrogen that is absorbed by the metal with time is given by the reaction rate, which is expressed as:

For absorption:

$$\frac{dx}{dt} = C_a \exp\left(-\frac{E_a}{RT}\right) \ln\left(\frac{P_a}{P_{eq}}\right) \left(1 - \frac{m_{MH}}{m_s}\right) \quad (4)$$

For desorption:

$$\frac{dx}{dt} = C_d \exp\left(-\frac{E_d}{RT}\right) \ln\left(\frac{P_d - P_{eq}}{P_{eq}}\right) \left(\frac{m_{MH}}{m_s}\right) \quad (5)$$

#### II.4. Equilibrium pressure

For absorption:

$$P_{eq} = \left[ \frac{\Delta S_d}{R} - \frac{\Delta H_d}{RT} + (\varphi_s + \varphi_0) \tan\left(\pi\left(\frac{x}{x_m} - \frac{1}{2}\right)\right) + \frac{\varphi}{2} \right] 10^5 \quad (6)$$

For desorption:

$$P_{eq} = \left[ \frac{\Delta S_d}{R} - \frac{\Delta H_d}{RT} + (\varphi_s - \varphi_0) \tan\left(\pi\left(\frac{x}{x_m} - \frac{1}{2}\right)\right) - \frac{\varphi}{2} \right] 10^5 \quad (7)$$

#### II.5. Energy equation

The energy equation could be expressed as follow:

For absorption:

$$\left(m_{H_2} C_{pH_2} + m_s C_{ps}\right) \frac{dT}{dt} = \dot{m}_{in} C_{pH_2} (T_{in} - T) + AU \left( T_{wd} - T \right) - \frac{\Delta H_d S C m_s dx}{MW_{MH} dt} \quad (8)$$

For desorption:

$$\left(m_{H_2} C_{pH_2} + m_s C_{ps}\right) \frac{dT}{dt} = AU (T_{wd} - T) + \frac{\Delta H_d S C m_s dx}{MW_{MH} dt} \quad (9)$$

#### II.6. Initial conditions

Initially, at absorption cycle the temperature, pressure, and the metal hydride mass in the tank are assumed to be constant:

$$T_{in} = T_{wa} ; P_s = P_0 \quad \text{and} \quad m_s = m_{s0} \quad (10)$$

In adsorption cycle the temperature of the reactor is equal to the heating water temperature  $T_d = T_{wd}$

### III. RESULTS AND DISCUSSION

The present analysis is carried out using a cylindrical reactor of having 27mm internal diameter with 3mm wall thickness and 450mm length [1].

Thermo-physical properties of the hydriding alloy and various constants used in the mathematical modeling are listed in Table 1.

Table 1 shows the thermo-physical properties of metal hydrides, properties of hydrogen and constants used in the analysis [1].

Table 1 – List of parameters used in the analysis [1]

Quantity	Value
<b>Reactor geometry</b>	
Length of the cylinder (mm)	475
Inner radius of inner cylinder (mm)	4.5
Inner radius of outer cylinder (mm)	12
Thickness of cylinder wall (mm)	3
<b>Properties</b>	
Initial and inlet temperature, $T_0$ & $T_{in}$ (°C)	20
Pressures, $P$ (bar)	10.0
Porosity of the hydride bed, $\varepsilon$	0.5
Permeability of the hydride bed $K$ ( $m^2 \cdot 10^{-8}$ )	
Thermal conductivity of the bed, $k_e$ (W/m.K)	1.6
Specific heat capacities, $C_p$ (J/kg.K)	419
Activation energy, $E_a$ (J/mol)	21170
Density of the hydride, $\rho$ (kg/m <sup>3</sup> )	8400
Reaction constant, $C_a$ (1/s)	100
<b>Properties of hydrogen</b>	
Thermal conductivity of hydrogen, (W/m K)	0.1272
Specific heat of hydrogen, (J/kg K)	14500
Density of hydrogen, (kg/m <sup>3</sup> )	0.0838
<b>Constants</b>	
Universal gas constant (J/mol K)	8.314
Slope factor ( $\varphi_s$ )	0.35
Constant ( $\varphi_0$ )	0.15

$\varphi$

Ghardaïa - Algeria 24-25 Octobre 2016

Figs. 3 and 4 showed that the numerically predicted averaged bed temperature profile and hydrogen storage capacity at a constant supply pressure of 35 bar, and water inlet temperature of 25 °C are in good agreement with the experimental results reported by Muthukumar et al. [1].

Figs. 2 – Comparison between experimental data [1] and numerical results of absorption at constant supply pressure (35 bars) on hydrogen storage capacity (A) and averaged bed temperature (B).

Figs. 2 illustrate the effect of supply pressure on hydrogen storage capacity and averaged bed temperature, a lower supply pressures determine lower amounts of absorbed hydrogen, due to the hydrating reaction kinetics. Lower temperatures are also reached.

Figs. 3 – Effect of supply pressure on hydrogen storage capacity (A) and averaged bed temperature (B).

Figs. 3 present the effect of cooling fluid temperature at constant supply pressure on hydrogen storage capacity and averaged bed temperature, it is clear to observe from equation (6) that the bed temperature influences the hydride equilibrium pressure. Hence, for a lower temperature allow for higher amounts of hydrogen to be absorbed.

Fig. 4 – Effect of cooling fluid temperature on hydrogen storage capacity (A) and averaged bed temperature (B).

Fig. 5 show that the predicted average bed temperature profiles during desorption process match closely with the experimental data reported by Muthukumaret al. [1]. Due to the poor thermal conductivity of the metal hydride, the necessary amount of heat is not transferred to the metal hydride bed. Hence, the hydride bed takes the heat from the bed itself and starts to desorb the hydrogen.

Fig. 5 – Comparison between experimental data [1] and numerical results of desorption at constant supply pressure (1 bar) on hydrogen storage capacity.

The results obtained for  $MmNi_{4.6}Fe_{0.4}$  hydride beds during the desorption process are presented in fig. 6 at different hot fluid temperatures varying from 30 to 50 °C.

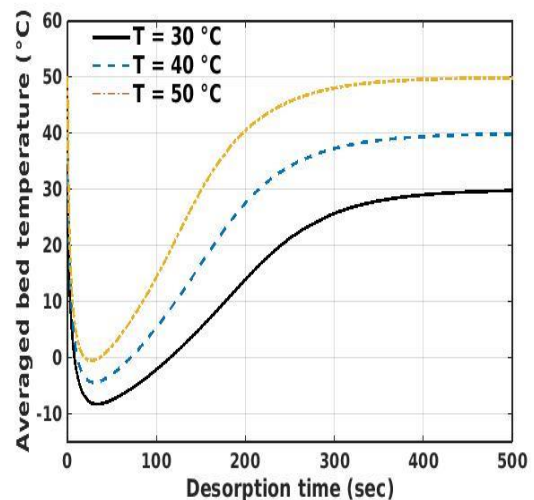

Fig. 6 - Desorption at constant discharge pressure (1 bar), comparison between experimental data [1] and numerical results.

## VI. CONCLUSION

In this study, a lumped model of a metal hydride hydrogen storage system has been developed, to simulate the hydrogen storage system at different supply pressures, cooling fluid temperatures, containing the alloy  $MmNi_4.6Fe_0.4$ . The temperature and concentration profiles are reported. The numerical results showed good agreement with the experimental data reported in the literature.
